

# S1: Percolation

*This assignment can be done in groups of 2.*

Write a program to estimate the value of the *percolation threshold* via Monte Carlo simulation.

**Percolation.** Given a composite systems comprised of randomly distributed insulating and metallic materials: what fraction of the materials need to be metallic so that the composite system is an electrical conductor? Given a porous landscape with water on the surface (or oil below), under what conditions will the water be able to drain through to the bottom (or the oil to gush through to the surface)? Scientists have defined an abstract process known as *percolation* to model such situations.

**The model.** We model a percolation system using an  $N$ -by- $N$  grid of *sites*. Each site is either *open* or *blocked*. A *full* site is an open site that can be connected to an open site in the top row via a chain of neighboring (left, right, up, down) open sites. We say the system *percolates* if there is a full site in the bottom row. In other words, a system percolates if we fill all open sites connected to the top row and that process fills some open site on the bottom row. (For the insulating/metallic materials example, the open sites correspond to metallic materials, so that a system that percolates has a metallic path from top to bottom, with full sites conducting. For the porous substance example, the open sites correspond to empty space through which water might flow, so that a system that percolates lets water fill open sites, flowing from top to bottom.)

**The problem.** In a famous scientific problem, researchers are interested in the following question: if sites are independently set to be open with probability  $p$  (and therefore blocked with probability  $1 - p$ ), what is the probability that the system percolates? When  $p$  equals 0, the system does not percolate; when  $p$  equals 1, the system percolates. The plots below show the site vacancy probability  $p$  versus the percolation probability for 20-by-20 random grid (left) and 100-by-100 random grid (right).

When  $N$  is sufficiently large, there is a *threshold* value  $p^*$  such that when  $p < p^*$  a random  $N$ -by- $N$  grid almost never percolates, and when  $p > p^*$ , a random  $N$ -by- $N$  grid almost always percolates. No mathematical

solution for determining the percolation threshold  $p^*$  has yet been derived. Your task is to write a computer program to estimate  $p^*$ .

**Percolation data type.** To model a percolation system, create a data type `Percolation` with the following API:

```
public class Percolation {
    public Percolation(int N)           // create N-by-N grid, with all
    sites initially blocked
    public void open(int row, int col)   // open the site (row, col) if
    it is not open already
    public boolean isOpen(int row, int col) // is the site (row, col) open?
    public boolean isFull(int row, int col) // is the site (row, col) full?
    public int numberOfOpenSites()       // number of open sites
    public boolean percolates()         // does the system percolate?
    public static void main(String[] args) // unit testing (required)
}
```

*Corner cases.* By convention, the row and column indices are integers between 0 and  $N - 1$ , where  $(0, 0)$  is the upper-left site: Throw a `java.lang.IndexOutOfBoundsException` if any argument to `open()`, `isOpen()`, or `isFull()` is outside its prescribed range. The constructor should throw a `java.lang.IllegalArgumentException` if  $N \leq 0$ .

*Performance requirements.* The constructor should take time proportional to  $N^2$ ; all methods should take constant time plus a constant number of calls to the union-find methods `union()`, `find()`, `connected()`, and `count()`.

*Note.* You should implement all of these, and only these, public methods. (You may introduce private methods as needed.) Your `main()` function should test all the methods (see the FAQ).

**Monte Carlo simulation.** To estimate the percolation threshold, consider the following computational experiment:

- Initialize all sites to be blocked.
- Repeat the following until the system percolates:
  - Choose a site uniformly at random among all blocked sites.
  - Open the site.
- The fraction of sites that are opened when the system percolates provides an estimate of the percolation threshold.

For example, if sites are opened in a 20-by-20 grid according to the snapshots below, then our estimate of the percolation threshold is  $204/400 = 0.51$  because the system percolates when the 204th site is opened.

50 open sites

100 open sites

150 open sites

204 open sites

By repeating this computation experiment  $T$  times and averaging the results, we obtain a more accurate estimate of the percolation threshold. Let  $x_t$  be the fraction of open sites in computational experiment  $t$ . The

sample mean  $\mu$  provides an estimate of the percolation threshold; the sample standard deviation  $\sigma$  measures the sharpness of the threshold.

$$\mu = \frac{x_1 + x_2 + \cdots + x_T}{T}, \quad \sigma^2 = \frac{(x_1 - \mu)^2 + (x_2 - \mu)^2 + \cdots + (x_T - \mu)^2}{T - 1}$$

Assuming  $T$  is sufficiently large (say, at least 30), the following provides a 95% confidence interval for the percolation threshold:

$$\left[ \mu - \frac{1.96\sigma}{\sqrt{T}}, \mu + \frac{1.96\sigma}{\sqrt{T}} \right]$$

To perform a series of computational experiments, create a data type `PercolationStats` with the following API.

```
public class PercolationStats {
    public PercolationStats(int N, int T)    // perform T independent
    experiments on an N-by-N grid
    public double mean()                    // sample mean of percolation
    threshold
    public double stddev()                  // sample standard deviation of
    percolation threshold
    public double confidenceLow()           // low endpoint of 95%
    confidence interval
    public double confidenceHigh()          // high endpoint of 95%
    confidence interval
}
```

The constructor should throw a `java.lang.IllegalArgumentException` if either  $N \leq 0$  or  $T \leq 0$ .

The constructor should take two arguments  $N$  and  $T$ , and perform  $T$  independent computational experiments (discussed above) on an  $N$ -by- $N$  grid. Using this experimental data, it should calculate the mean, standard deviation, and the 95% *confidence interval* for the percolation threshold. Use [StdRandom](#) to generate random numbers; use [StdStats](#) to compute the sample mean and standard deviation.

```
Example values after creating PercolationStats(200, 100)
mean()                = 0.5929934999999997
stddev()              = 0.00876990421552567
confidenceLow()       = 0.5912745987737567
confidenceHigh()      = 0.5947124012262428
```

```
Example values after creating PercolationStats(200, 100)
mean()                = 0.592877
stddev()              = 0.009990523717073799
confidenceLow()       = 0.5909188573514536
confidenceHigh()      = 0.5948351426485464
```

```
Example values after creating PercolationStats(2, 100000)
mean()                = 0.6669475
stddev()              = 0.11775205263262094
confidenceLow()       = 0.666217665216461
confidenceHigh()      = 0.6676773347835391
```

## Analysis of running time.

- Implement the `Percolation` data type using the *quick-find* algorithm in [QuickFindUF](#). Use [Stopwatch](#) to measure the total running time of `PercolationStats` for various values of  $N$  and  $T$ . How does doubling  $N$  affect the total running time? How does doubling  $T$  affect the total running time? Give a formula (using tilde notation) of the total running time on your computer (in seconds) as a single function of both  $N$  and  $T$ .

- Now, implement the `Percolation` data type using the *weighted quick-union* algorithm in [WeightedQuickUnionUF](#). Answer the same questions in the previous bullet.

**Deliverables.** Submit in Canvas `Percolation.java` (using the weighted quick-union algorithm from [WeightedQuickUnionUF](#)) and `PercolationStats.java`. These should first be tested on Mooshak. Your submissions may not call library functions except those in [StdIn](#), [StdOut](#), [StdRandom](#), [StdStats](#), [WeightedQuickUnionUF](#), and `java.lang`.

**Checklist.** See the associated S1 Checklist document for a FAQ; clients and data for testing; and ideas for possible progress steps.

**Report.** The experiments is to be described in a report following a template supplied. This will be given as a separate assignment, due 9 September.
